Subject: EVRAZ Oregon Steel 2015 Beach and Bank Groundwater Monitoring Report

Dear Ms. Sutter:

In January 2015, EVRAZ Oregon Steel (EOS) sampled groundwater in select beach and bank monitoring wells at its Rivergate facility in Portland, Oregon. Sampling was conducted per an Oregon Department of Environmental Quality (DEQ) letter, dated March 22, 2013, requiring resampling of six wells that were likely impacted by a leak in the Willamette River water make-up line (river water line) during the September 2012 sampling event.

September 2012 groundwater concentrations in selected wells were affected by the river water line leak. With the exception of MW-13, water level and field parameter measurements (pH, conductivity, and temperature) since that time show that groundwater has essentially stabilized to pre-leak conditions. In MW-13, water levels and field parameter measurements have been generally stable over the past year. As compared to pre-leak conditions, seasonal water levels are approximately 4 ft higher, pH is approximately 3 units higher, and conductivity is approximately half of the pre-leak values. Temperature is similar to pre-leak conditions. Based on this stability over the past year and the pending well abandonment for the Riverbank source control measure, the DEQ-required sampling was completed in January 2015.

January 2015 groundwater concentrations were generally similar to or slightly less than those from pre-2012 sampling events. The exceptions were in monitoring well MW-17, where nickel was an order of magnitude higher than the pre-2012 sampling results, and in monitoring well MW-13, where manganese was 2 orders of magnitude lower than the

Ms. Jennifer Sutter

Page 2

pre-2012 sampling results. This letter presents results of the January 2015 sampling and supports DEQ's groundwater source control decision recommendation of "no further action" (NFA) (DEQ 2013).

BACKGROUND

In 2005, EOS conducted a groundwater source control evaluation (SCE) to assess metals concentrations in groundwater at its Rivergate facility and evaluate the potential for these concentrations to reach Willamette River receptors at unacceptable levels. Bank wells were used to assess groundwater quality in a shallow, water-bearing zone on the upland portion of the riverbank, at the downgradient edge of the steel mill. Beach wells, located farther downgradient on the upper beach near the river's edge, were used to assess the potential for complete transport pathways from the upland portion of the shallow aquifer to the Willamette River (RETEC 2006a) and provide transition zone water (TZW)-equivalent data.

The 2005 SCE identified five metals at concentrations exceeding selected joint source control strategy (JSCS) screening level values (SLVs) in beach wells: arsenic, cadmium, lead, manganese, and nickel (RETEC 2006b). Differences between the lowest JSCS SLVs and beach groundwater for cadmium, lead, and nickel were slight, while arsenic and manganese concentrations were higher in comparison to SLVs. Metals concentrations in beach groundwater are consistent with TZW concentrations observed at other sites that have been evaluated as part of the U.S. Environmental Protection Agency's (EPA's) Portland Harbor groundwater pathway assessment program (RETEC 2006a).

Selected site monitoring wells have been sampled in 2002, 2005, 2008, 2009 and 2012. The 2012 sampling included all bank and beach monitoring wells and one background well to confirm consistent concentrations with previous results. Results from the September 2012 beach and bank groundwater monitoring indicated that metals concentrations were largely stable or declining slightly, compared to concentrations from previous monitoring events (Integral 2013). However, in the vicinity of monitoring wells MW-10 and MW-13 metals concentrations were significantly lower and groundwater elevations were unusually high due to a leak in the river water line. The leak of river water from the river water line was identified during the September 2012 sampling event and repaired when access was feasible in March 2013.

To better understand groundwater concentrations in the MW-10/MW-13 area without the influence of the leak, DEQ required an additional round of sampling from three bank wells and three beach wells. The sampling was to be completed after the river water line was repaired and groundwater stabilized to pre-leak conditions. In e-mail communications

with the DEQ in September 2013 (Integral and DEQ 2013), DEQ-required groundwater sampling was planned for after the following parameters returned to levels considered representative of pre-leak conditions in MW-13:

- Stabilized groundwater pH below 7
- Stabilized groundwater conductivity above 500 $\mu\text{mhos}/\text{cm}$
- Stabilized groundwater temperature similar (+/- 20%) to events prior to September 2012
- Groundwater elevation in MW-13 down to within 1.5 ft of pre-leak measurements.

Groundwater field parameters were monitored periodically from well MW-13, and water levels were generally measured quarterly from wells MW-9, MW-10, MW-13, MW-17, MW-18, and MW-23 beginning in July 2013¹. Results of this monitoring are provided in Attachment A. With the exception of MW-13, groundwater elevations of wells in the vicinity of the river water line leak had returned to pre-leak elevations by September 2013.

On October 30, 2014, the pH of groundwater from MW-13 was 9.9, conductivity was 208 $\mu\text{mhos}/\text{cm}$, temperature was within 23%, and the groundwater elevation was approximately 4 ft higher than pre-leak conditions. These measurements are generally consistent with the October 2013 measurements, suggesting stable conditions but somewhat different from conditions prior to the leak. DEQ and EOS agreed to complete the DEQ-required sampling in January 2015 since the leak was repaired 22 months prior, conditions had stabilized, and wells will be decommissioned in summer 2015 as part of the Riverbank source control measure. Results from the required post-stabilization sampling, completed in January 2015, are the subject of this letter report.

METHODS

Field Procedures

Groundwater was sampled on January 19 and 20, 2015. The work was completed in accordance with the site-specific field sampling plan (Appendix A to the remedial investigation work plan; Exponent 2002) and the quality assurance project plan (QAPP)

¹ Water levels from wells MW-17, MW-18, and MW-23 were not measured during the first quarter of 2014.

Ms. Jennifer Sutter

August 6, 2015

Page 4

(RETEC 2005), with minor revisions detailed below. The monitoring program included six wells:

- Bank wells MW-9, MW-10, and MW-13
- Beach wells MW-17, MW-18, and MW-23.

Monitoring well locations are shown on Figures 1 through 5.

Prior to groundwater sampling, depth to groundwater was measured in all wells with an electronic water level probe. Wells were purged, and groundwater samples were collected using low-flow sampling techniques. All wells except MW-9 and MW-13 were sampled using a peristaltic pump; wells MW-9 and MW-13 were sampled using a bladder pump, due to the greater depth to water in comparison to the other wells.

For wells sampled using the peristaltic pump, care was taken to adjust the flow rate to maintain well drawdown at less than 0.3 ft. Disposable tubing was used and replaced with clean tubing between sampling locations. For MW-9 and MW-13, the decontaminated bladder pump was operated at a flow rate of 0.15 L per minute, to maintain well drawdown at less than 0.3 ft.

Field parameters (pH, conductivity, temperature, redox potential, dissolved oxygen, and turbidity) were monitored every 5 minutes during groundwater purging, prior to sampling each well. Parameters were considered stable when each parameter was within 10% for three consecutive readings, except for pH, which was considered stable when readings were within ± 0.1 unit for three readings. Completed groundwater field forms are provided in Attachment B. Water was purged from each well until field parameter stability was attained. Therefore, total water volume purged from each well varied.

Samples were collected for select total and dissolved metals, alkalinity, sulfate, total suspended solids, hardness, and dissolved organic carbon (DOC). Dissolved metals and DOC sample bottles were filled by field-filtering groundwater through a 0.45- μm filter. Samples were immediately sealed in Ziploc® bags and placed in a cooler with ice for transport under chain of custody to the ALS Environmental laboratory in Kelso, Washington, within 48 hours of collection. The following analytical methods were used:

- Total and dissolved arsenic, cadmium, lead, manganese, and nickel by EPA method 6020A
- Total calcium, magnesium, potassium, and sodium by EPA method 6010C
- Total suspended solids by standard method (SM) 2540D

- Chloride and sulfate by EPA method 300.0
- Alkalinity by SM 2320B
- Hardness as CaCO₃ by SM 2340B
- DOC by EPA method 415.1.

Completed chain-of-custody forms and laboratory reports are included in Attachment C.

Quality Assurance/Quality Control

Project quality assurance and quality control (QA/QC) procedures are discussed in Appendix B of the *Riverbank Source Control Evaluation Work Plan* (RETEC 2005). QA/QC samples were collected as part of the field effort. One field duplicate groundwater sample was collected during the sampling event to meet the standard of one duplicate per 20 field samples, as identified in the QAPP. The duplicate groundwater sample was collected by filling two consecutive sample bottles for each analyte. The field duplicate was not identified as a duplicate on the sample labels or chain-of-custody form but was identified as such in the field notebook and the sample logs. The field duplicate was analyzed for the same parameters as the investigative samples.

Data Quality

The data validation report presents an evaluation of precision, accuracy, method compliance (laboratory procedures and data management), completeness of the data set, and a summary of validation qualifiers assigned during this review (Attachment D). Precision, accuracy, method compliance, and completeness of the data set have been determined to be acceptable based on the data reported. Groundwater data have been determined to be usable for the purpose of assessing the presence (or absence) and concentrations of the analytes in groundwater.

RESULTS

Sampling was completed in 2012 to demonstrate that groundwater concentrations were relatively stable in beach and bank wells. Results showed stable or decreasing concentrations with the exception of wells influenced by the river water line leak. The three beach wells and three bank wells with the highest potential for groundwater quality to be affected by the river water line leak were again sampled in January 2015 per DEQ request. As discussed in Attachment A, with the exception of MW-13, field parameters

Ms. Jennifer Sutter

August 6, 2015

Page 6

indicated wells had stabilized to pre-leak conditions. Sampling was conducted to assess whether metals concentrations in the vicinity of the former leak are either stable or decreasing relative to previous results (2005 through 2009 and not including September 2012 when groundwater quality was affected by the leak).

Selected metals groundwater results are provided in Table 1 and are compared to 2005 through 2009 and to 2012 results in Tables 2 and 3, respectively. Groundwater quality data dating back to 2002 are provided on Figures 1 through 8. Geochemical parameters are included in Table 4. Laboratory analytical reports are included in Attachment C. Groundwater level information is provided in Table 5.

Groundwater Levels

The January 2015 groundwater elevations in all beach and bank wells in the vicinity of the river water line leak are within the range of elevations observed during monitoring events prior to 2012 (Table 5). Groundwater elevations in bank wells MW-10 and MW-13, the wells most significantly impacted by the river water line leak, have dropped more than 3 ft since September 2012. The January 2015 groundwater elevation at MW-13 is 3.2 to 5.7 ft higher than it was during pre-leak (2005–2008) winter measurements (December–February; Attachment A). The January 2015 groundwater elevation in MW-10 is within the range of previous winter measurements.

Groundwater Quality

The 2015 groundwater quality results are generally similar or slightly less than those from pre-2012 sampling events. The exceptions are monitoring well MW-17, where nickel was less than an order of magnitude higher than the pre-2012 sampling results, and monitoring well MW-13, where manganese was 2 orders of magnitude lower than the pre-2012 sampling results.

The nickel concentration in MW-17 is considered anomalous and is likely not be representative of long-term conditions. The concentration is less than an order of magnitude above historical concentrations and upgradient concentrations. Review of laboratory data and procedures did not identify a clear reason for the anomalous concentration in monitoring well MW-17. However, MW-17 is located immediately downgradient of MW-13, the well with the most significant river water line leak effects that has not fully recovered to pre-leak conditions. While field parameters in MW-17 are similar to pre-leak conditions, nickel concentrations are likely ephemeral and influenced by dissolution/desorption from phases that were stable during the leak. The lower manganese

concentration in MW-13 is also likely related to as-yet-incomplete equilibration to pre-leak conditions in this area. The January 2015 alkalinity, chloride, and calcium in MW-13 are also lower than the 2005 results.

January 2015 total and dissolved metals concentrations are very similar. Only lead and manganese concentrations in MW-13 show a variation, but it is less than an order of magnitude (Table 1).

GROUNDWATER QUALITY DISCUSSION

This section compares groundwater quality to various criteria including the June 5, 2015 EPA draft Preliminary Remedial Goals (PRGs) for the Portland Harbor Feasibility Study (EPA draft PRGs), PRG values revised to consider sample-specific hardness, and the JSCS SLVs (Table 3-1 in DEQ and USEPA 2005, revised 2007). A. Liverman of DEQ indicated in a June 23, 2015 meeting that EPA draft PRGs, when finalized, will supersede the JSCS SLVs. Both EPA draft PRGs and JSCS SLVs are included in this discussion for completeness. Additional perspective is provided by comparing beach well concentrations to TZW concentrations elsewhere in Portland Harbor and to Portland Harbor surface water concentrations (Integral et al 2011).

Groundwater from beach wells is considered equivalent to TZW and, therefore, screening against EPA draft PRGs, hardness adjusted PRGs, JSCS SLVs, and TZW or pore water in Portland Harbor is relevant. Bank wells are located upgradient of beach wells on the inland side of the berm, and groundwater concentrations vary between bank and beach wells due to attenuation, geochemical transformation associated with variations in redox potential, pH, alkalinity, and organic carbon and localized site conditions. Screening levels (EPA draft PRGs, hardness adjusted PRGs, and JSCS SLVs) are not directly applicable to bank wells as this groundwater is not near the point of discharge to the river and comparisons to these levels are presented for reference only. Beach wells, located between berm wells and the surface water, are more appropriately screened against these levels.

Screening criteria for cadmium, lead, and nickel are based on, and therefore compared to, dissolved concentrations. For arsenic and manganese, the SLVs do not specify whether they are for comparison to total or dissolved concentrations. Therefore, criteria are conservatively compared to total metals concentrations.

Arsenic

All 2015 arsenic concentrations in bank and beach wells exceed both the EPA draft PRG and the lower JSCS SLV (Figure 1). However, these criteria are set below background concentrations measured upgradient of the EOS facility and regionally (2 µg/L; DEQ 2002).

Both the EPA draft PRG and the JSCS SLV for arsenic include human consumption of water. The EPA draft PRG is based on human consumption of water and seafood, and the JSCS SLV is an EPA tap water² screening level. Screening levels based on consumption of drinking water are overly conservative and not relevant to site uses. Drinking water is not a beneficial use of the upland shallow water-bearing zone at EOS (Exponent 2004). Upon discharge of groundwater to surface water, the potential uses of the Willamette River could theoretically include drinking water. However, there is no current or expected future use of this portion of the Willamette River as a water supply, and conventional treatment of river water would be necessary prior to using it as drinking water.³

Ecological risk was not associated with arsenic in the Baseline Ecological Risk Assessment for Portland Harbor (Windward 2013).

While beach groundwater concentrations exceed screening values based on human consumption of seafood, they are consistent with levels for TZW in Portland Harbor and do not affect river water quality. Arsenic concentrations in beach wells are consistent with arsenic in Portland Harbor TZW (Figure 2 and Attachment E). While TZW studies were implemented at sites with contaminated groundwater, the sampling also included reference areas not in the groundwater plumes (Figure E-1).

The river water arsenic concentrations measured off the EOS facility are comparable to those measured upstream in Portland Harbor, indicating that background TZW concentrations are not adversely affecting the water column.

Given the background concentrations of arsenic, and similar river concentrations upstream and off EVRAZ, arsenic in EOS groundwater is not adversely affecting Portland Harbor.

² Note that arsenic concentrations in 2015 beach groundwater samples are below the Drinking Water Maximum Contaminant Level of 10 µg/L

³ “Public domestic water supply” and “private domestic water supply” are among the designated beneficial uses of the Lower Willamette River; however, both uses are specifically qualified with the condition, “with adequate pretreatment and natural quality that meets drinking water standards” (Oregon Administrative Rules [OAR] 340-041-0340, Table 340A).

Cadmium and Lead

Dissolved cadmium and lead concentrations in bank and beach wells are below the EPA draft PRGs and JSCS SLVs. Both the EPA draft PRG and the JSCS SLV are based on the National Recommended Water Quality Criteria (NRWQC) and calculated considering receiving water hardness (Figures 3 and 4). These criteria use a hardness value (25 mg/L) lower than that in Portland Harbor TZW (typically >100 mg/L), and therefore they are conservative.

Cadmium and lead concentrations measured in EOS groundwater are not adversely affecting receptors in Portland Harbor.

Manganese

Manganese concentrations in most bank and all beach wells exceed the EPA draft PRG and the JSCS SLV, which are both set at a National Secondary Drinking Water Standard related to aesthetics and water taste (Figure 5). The standard is not risk-based and thus does not indicate adverse effects to receptors. Secondary maximum contaminant levels are established only as guidelines to assist public water systems in managing their drinking water for aesthetic considerations, such as taste, color, and odor. Because site groundwater and the Willamette River are not used for drinking water, this standard is not applicable to beach groundwater.

Beach groundwater can also be compared to hardness-adjusted ecological criteria for manganese in TZW using the approach and calculations documented by Windward (Windward 2014). The ecological toxicity of manganese is sensitive to hardness. As shown on Figure 6, all three beach well concentrations and one of the three bank wells plot below hardness-based criteria indicating that the manganese in groundwater does not pose unacceptable ecological risk.

Consistent with this consideration of hardness, geochemical testing has shown that manganese behavior is largely controlled by localized geochemistry. As discussed in the metals in groundwater SCE (RETEC 2006b), metals in TZW must be interpreted in the context of local geochemical conditions. Consistent with previous sampling events,⁴ manganese concentrations in the central and southern portions of the beach are similar or higher than in paired upgradient bank wells. This is particularly evident in localized areas where slag is prevalent in the upper beach (e.g., immediately north of the dock). This slag

⁴ Excluding the September 2012 river water line leak event

is being removed as part of the Riverbank source control measure, and beach groundwater concentrations are expected to decrease. Nevertheless, hardness correction indicates manganese is not reaching the river at concentrations which will adversely affect receptors.

The manganese EPA draft PRG and JSCS SLV are lower than concentrations in background well MW-22 and are within the range of results from the Portland Harbor TZW study (Figure 7 and Attachment E). The geochemical processes mediating the concentrations in Portland Harbor TZW were studied and modeled in the Portland Harbor Remedial Investigation. Manganese was found to be a ubiquitous metal in TZW and predominantly reflects the local geochemical conditions of the sediment TZW environment and is independent of migration of upland groundwater plumes. Manganese in TZW at concentrations above the screening levels is likely derived from reductive dissolution of sedimentary manganese oxides, and appears to be maintained at approximate equilibrium with rhodochrosite or other manganese-bearing carbonate mineral (e.g., calcite) (Integral et al. 2011).

Human health criteria for manganese are not risk-based and not applicable to beach groundwater. Manganese does not exceed ecological risk-based criteria using sample-specific hardness, and manganese is present as a background metal. Based on the lack of risk and ubiquitous manganese concentrations in TZW, mediated by local geochemistry and unrelated to groundwater plumes, the groundwater at EOS is not adversely affecting the river.

Nickel

EPA determined, through the baseline human health and ecological risk assessments for Portland Harbor, that nickel does not pose unacceptable risk. Therefore, an EPA draft PRG was not developed. Dissolved nickel concentrations in the three bank wells and two of the three beach wells are below the JSCS SLV (Figure 8). Previous sampling events indicate the concentration in beach well MW-17 is generally below the JSCS SLV, but exceeded the JSCS SLV during the January 2015 sampling event by a factor of approximately 6. This anomalous result is likely the result of an ephemeral condition related to the river water line leak and not related to long-term concentrations.

As nickel does not pose unacceptable risk in Portland Harbor and the detection in MW-17 is likely to be ephemeral, nickel in EOS beach wells is not adversely affecting Portland Harbor.

SUMMARY

In January 2015, EOS sampled three bank and three beach monitoring wells in the vicinity of a 2012 river water line leak at its Rivergate facility. The leak was repaired in early 2013, and with the exception of MW-13, groundwater elevations and field parameters have stabilized to pre-leak conditions. Data from the January 2015 sampling event, in conjunction with September 2012 monitoring data for bank and beach wells not impacted by the leak, provide a complete data set for metals in groundwater. January 2015 sampling results show that groundwater conditions are stable or decreasing, as follows:

- Groundwater concentrations in beach and bank monitoring wells are generally consistent with or less than 2005–2009 results, prior to the leak. With the exception of nickel in MW-17, metals concentrations that exceed 2005 results are within a factor of 2. For MW-17, the nickel concentration exceeds 2005 results by a factor of 6.
- Monitoring wells MW-10, MW-13, and MW-17 showed a significant decrease in manganese and nickel concentrations during 2012 sampling (AECOM and Integral 2013); 2015 results indicate that the groundwater concentrations have predominantly returned to stable conditions since the leak was repaired:
 - MW-10: Concentrations are consistent with pre-leak concentrations.
 - MW-13: The manganese concentration remains 2 orders of magnitude below pre-leak concentrations; the nickel concentration has increased by an order of magnitude since September 2012 but remains slightly below pre-leak concentrations.
 - MW-17: Nickel concentrations are an order of magnitude higher than pre-leak concentrations, and are expected to be ephemeral and related to conditions not fully recovered in the vicinity of upgradient well MW-13.
- Beach groundwater quality is representative of TZW, and the only metals with exceedances of EPA draft PRGs are arsenic and manganese. However, these groundwater concentrations do not pose unacceptable risk in Portland Harbor.
 - While arsenic concentrations in beach wells exceed criteria based on human consumption of organisms, they are consistent with TZW concentrations observed at other sites that have been evaluated as part of EPA's Portland Harbor groundwater pathway assessment program and do not affect surface water quality off EOS. Surface water concentrations off EOS are comparable to concentrations upstream in Portland Harbor.

Ms. Jennifer Sutter

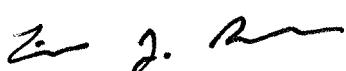

August 6, 2015

Page 12

- Manganese concentrations, when corrected for hardness, are below risk-based concentrations. Concentrations in beach groundwater are consistent with TZW concentrations observed at other sites that have been evaluated as part of EPA's Portland Harbor groundwater pathway assessment program and are controlled by localized geochemical conditions.

January 2015 bank and beach groundwater monitoring results indicate that metals concentrations are generally stable or declining compared to 2005 to 2009 data. Cadmium, lead, and nickel are below EPA draft PRGs. With hardness corrections, manganese concentrations are below risk-based criteria. Arsenic is present as a background metal in surface water and TZW. Arsenic concentrations in surface water off EOS are comparable to upstream concentrations and are not being adversely affected by EOS beach groundwater. The January 2015 data support the NFA recommendation for groundwater at EOS, drafted by DEQ in April 2013.

Sincerely,

Linda Baker

Bold indicates detection above method detection limit.

yellow beach well with concentrations exceeding screening level value used for initial upland source control evaluations of water (JSCS Table 3-1, 7/16/07); where criterion is applicable to the dissolved fractions, total metals concentrations are not identified as exceedances.

< = analyte not detected at or above the method reporting limit

EPA = U.S. Environmental Protection Agency

MCL = Drinking Water Maximum Contaminant Level

NRWQC = national recommended water quality criteria

PRG/RSL = preliminary remediation goal/regional screening level

^a Aquatic Water Quality Criteria (water + organism)

^b EPA's 2004 NRWQC for ecological receptors and adopted as a Threshold Reference Value in the Portland Harbor Baseline Ecological Risk Assessment and used as a JSCS SLV; expressed in terms of dissolved metals; criteria are hardness dependent and assume a hardness of 25 mg/L.

^c Clean Water Act, 33 USC 1313 and 1314, Section 304(a) List; national secondary drinking water standard; this criterion is not based on toxic effects, but rather is intended to minimize objectionable qualities such as laundry stains and objectionable tastes in beverages.

^d Tap water PRG/RSL

^e EPA's 2004 NRWQC ecological receptors, expressed in terms of dissolved metals

ATTACHMENT A

2013-2014 FIELD PARAMETER MONITORING

ATTACHMENT A: 2013-2014 FIELD PARAMETER MONITORING

As reported in the EVRAZ Oregon Steel 2012 Beach and Riverbank Groundwater Monitoring Report (AECOM and Integral 2013), a leak in the Willamette River water intake line (the river water line) was discovered during the September 2012 monitoring well sampling event. Lower metals concentrations and anomalously high water levels were observed, indicating that groundwater in bank wells MW-10 and MW-13 and beach well MW-17 were impacted by the leak. September 2012 metals concentrations in most monitoring wells were similar to previous pre-leak monitoring concentrations; however, nickel and manganese concentrations in MW-10, MW-13, and MW-17 were one or more orders of magnitude lower than previous events (see Tables 2 and 3 of AECOM and Integral 2013). In addition to the lower nickel and manganese concentrations, MW-13 groundwater field parameters (e.g., pH, conductivity, temperature) were notably different in September 2012 compared to conditions recorded during the September 2005 monitoring event.

	September 2005	September 2012	Percentage Difference
Water Elevation (ft NGVD29)	9.18	19.14	
pH (standard units)	6.62	8.32	20%
Conductivity ($\mu\text{mhos}/\text{cm}$)	474	174	272%
Temperature ($^{\circ}\text{C}$)	17.1	24.2	29%

As a result of the river water line leak, DEQ required sampling of six additional wells in its March 22, 2013 letter (DEQ 2013). Sampling was to be completed after repair to the river water line and following groundwater stabilization to pre-leak conditions. The river water line was repaired in March 2013 and water levels were monitored in select beach and berm wells periodically beginning in July 2013 (a minimum of quarterly). To further assess stabilization, groundwater field parameters were monitored quarterly in MW-13, the well closest to the leak beginning in September 2013. As stated in the attached email correspondence, DEQ agreed to the following approach for determining groundwater stabilization in MW-13, and subsequent sample collection from the six DEQ-requested wells:

- The stabilized groundwater pH is below 7
- The stabilized groundwater conductivity is above 500 $\mu\text{mhos}/\text{cm}$
- The stabilized groundwater temperature is similar (+/-20%) to events prior to September 2012.

Water level and field parameter monitoring results are provided on Table A-1. Water levels and field parameters were measured in October 2014, 19 months after repair of the river

water line leak. With the exception of MW-13, groundwater elevations in all monitored wells had recovered and were similar to pre-leak elevations. The groundwater elevation in MW-13 had decreased 5.6 feet since the leak was identified but remained approximately four feet higher than September 2005 elevation¹. October 2013 and October 2014 water elevations were very similar (less than a half foot difference in elevation). These measurements indicated that, from a physical perspective, groundwater had stabilized with an elevation approximately four feet above pre-leak conditions. Field parameters were also relatively stable over the last year of measurement. October 2014 field parameter measurements from MW-13 were as follows.

	September 2005	October 2014	Percent Difference
Level (above mean sea level; ft)	9.18	13.52	
pH (standard units)	6.62	9.9	33%
Conductivity ($\mu\text{mhos}/\text{cm}$)	474	208	228%
Temperature ($^{\circ}\text{C}$)	17.1	21.5	20%

While the October 2014 field parameter measurements did not meet the resampling criteria EOS established with DEQ, EOS and DEQ agreed to complete the DEQ-required sampling in January 2015. Sampling was completed to assess groundwater conditions since the leak repair was completed approximately 22 months prior, water levels and field parameters were relatively stable over the past year, and monitoring wells will be decommissioned in early summer 2015 for the Riverbank Source Control Measure.

Field parameters measured during the January 2015 sampling event are also provided on Table A-1. MW-13 field parameters from January 2015 groundwater sampling event showed:

- Relatively stable pH at values above pre-leak conditions
- A slightly higher conductivity, but still approximately half pre-leak conditions
- Temperature similar to pre-leak conditions.

MW-13 groundwater elevations are relatively stability with post-leak conditions over the past year (given seasonal variation) and are approximately four feet above pre-leak water levels.

¹ The October 2014 groundwater elevation was within the range of previous measurements, being less than the elevation measured in May 2008 and May 2009.

Table A-1. Historical Sampling Results Versus 2013-2015 Groundwater Levels

Source: Integral and AECOM (2013). EVRAZ Oregon Steel 2012 Beach and Riverbank Groundwater Monitoring Report

Notes:

=wells noted in Feb 2013 Integral/AECOM Beach & Riverbank GW Monitoring Report

=wells added by DEQ in the March 22, 2013 letter to investigate

=percent difference in field parameter measurements between monitoring events

September-05 or December-05 is the reference date for comparison ("historic" condition)

ft. amsl = feet above mean sea level

ft. bTOC = feet below top of casing

% diff = percent difference between dates shown

--=not measured

bold values represent the most recent measurements at each location^a Vertical reference datum is National Geodetic Vertical Datum (NGVD) of 1929

Analytical Report for Service Request No: K1500604

Craig Heimbucher
Integral Consulting, Inc.
319 SW Washington St.
Suite 1150
Portland, OR 97204

RE: Evraz Oregon Steel/C1144-0204

Dear Craig:

Enclosed are the results of the sample(s) submitted to our laboratory on January 21, 2015. For your reference, these analyses have been assigned our service request number **K1500604**.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program. The test results meet requirements of the current NELAP standards, where applicable, and except as noted in the laboratory case narrative provided. For a specific list of NELAP-accredited analytes, refer to the certifications section at www.alsglobal.com. All results are intended to be considered in their entirety, and ALS Group USA Corp. dba ALS Environmental (ALS) is not responsible for use of less than the complete report. Results apply only to the items submitted to the laboratory for analysis and individual items (samples) analyzed, as listed in the report.

Please contact me if you have any questions. My extension is 3363. You may also contact me via email at Lisa.Domenighini@alsglobal.com.

Respectfully submitted,

ALS Group USA Corp. dba ALS Environmental

A handwritten signature in blue ink that reads "Lisa S Domenighini".

Acronyms

ASTM	American Society for Testing and Materials
A2LA	American Association for Laboratory Accreditation
CARB	California Air Resources Board
CAS Number	Chemical Abstract Service registry Number
CFC	Chlorofluorocarbon
CFU	Colony-Forming Unit
DEC	Department of Environmental Conservation
DEQ	Department of Environmental Quality
DHS	Department of Health Services
DOE	Department of Ecology
DOH	Department of Health
EPA	U. S. Environmental Protection Agency
ELAP	Environmental Laboratory Accreditation Program
GC	Gas Chromatography
GC/MS	Gas Chromatography/Mass Spectrometry
LOD	Limit of Detection
LOQ	Limit of Quantitation
LUFT	Leaking Underground Fuel Tank
M	Modified
MCL	Maximum Contaminant Level is the highest permissible concentration of a substance allowed in drinking water as established by the USEPA.
MDL	Method Detection Limit
MPN	Most Probable Number
MRL	Method Reporting Limit
NA	Not Applicable
NC	Not Calculated
NCASI	National Council of the Paper Industry for Air and Stream Improvement
ND	Not Detected
NIOSH	National Institute for Occupational Safety and Health
PQL	Practical Quantitation Limit
RCRA	Resource Conservation and Recovery Act
SIM	Selected Ion Monitoring
TPH	Total Petroleum Hydrocarbons
tr	Trace level is the concentration of an analyte that is less than the PQL but greater than or equal to the MDL.

Inorganic Data Qualifiers

- * The result is an outlier. See case narrative.
- # The control limit criteria is not applicable. See case narrative.
- B The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
- E The result is an estimate amount because the value exceeded the instrument calibration range.
- J The result is an estimated value.
- U The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL.
DOD-QSM 4.2 definition : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
- i The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
- X See case narrative.
- Q See case narrative. One or more quality control criteria was outside the limits.
- H The holding time for this test is immediately following sample collection. The samples were analyzed as soon as possible after receipt by the laboratory.

Metals Data Qualifiers

- # The control limit criteria is not applicable. See case narrative.
- J The result is an estimated value.
- E The percent difference for the serial dilution was greater than 10%, indicating a possible matrix interference in the sample.
- M The duplicate injection precision was not met.
- N The Matrix Spike sample recovery is not within control limits. See case narrative.
- S The reported value was determined by the Method of Standard Additions (MSA).
- U The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL.
DOD-QSM 4.2 definition : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
- W The post-digestion spike for furnace AA analysis is out of control limits, while sample absorbance is less than 50% of spike absorbance.
- i The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
- X See case narrative.
- + The correlation coefficient for the MSA is less than 0.995.
- Q See case narrative. One or more quality control criteria was outside the limits.

Organic Data Qualifiers

- * The result is an outlier. See case narrative.
- # The control limit criteria is not applicable. See case narrative.
- A A tentatively identified compound, a suspected aldol-condensation product.
- B The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
- C The analyte was qualitatively confirmed using GC/MS techniques, pattern recognition, or by comparing to historical data.
- D The reported result is from a dilution.
- E The result is an estimated value.
- J The result is an estimated value.
- N The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.
- P The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.
- U The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL.
DOD-QSM 4.2 definition : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
- i The MRL/MDL or LOQ/LOD is elevated due to a chromatographic interference.
- X See case narrative.
- Q See case narrative. One or more quality control criteria was outside the limits.

Additional Petroleum Hydrocarbon Specific Qualifiers

- F The chromatographic fingerprint of the sample matches the elution pattern of the calibration standard.
- L The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of lighter molecular weight constituents than the calibration standard.
- H The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of heavier molecular weight constituents than the calibration standard.
- O The chromatographic fingerprint of the sample resembles an oil, but does not match the calibration standard.
- Y The chromatographic fingerprint of the sample resembles a petroleum product eluting in approximately the correct carbon range, but the elution pattern does not match the calibration standard.
- Z The chromatographic fingerprint does not resemble a petroleum product.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program. A complete listing of specific NELAP-certified analytes, can be found in the certification section at www.alsglobal.com or at the accreditation bodies web site.

Please refer to the certification and/or accreditation body's web site if samples are submitted for compliance purposes. The states highlighted above, require the analysis be listed on the state certification if used for compliance purposes and if the method/anlayte is offered by that state.

ALS ENVIRONMENTAL

Client: Integral Consulting, Incorporated
Project: Evraz Oregon Steel/ C1144-0204
Sample Matrix: Water **Service Request No.:** K1500604
 Date Received: 01/21/15

Case Narrative

All analyses were performed consistent with the quality assurance program of ALS Environmental. This report contains analytical results for samples designated for Tier III deliverables including summary forms for each of the analyses. When appropriate to the method, method blank results have been reported with each analytical test.

Sample Receipt

Eight water samples were received for analysis at ALS Environmental on 01/21/15. The samples were received in good condition and consistent with the accompanying chain of custody form. The samples were stored in a refrigerator at 4°C upon receipt at the laboratory.

General Chemistry Parameters

No anomalies associated with the analysis of these samples were observed.

Total and Dissolved Metals

Matrix Spike Recovery Exceptions:

The control criteria for matrix spike recovery of Manganese for sample GW2015011901 were not applicable. The analyzed concentration in the sample was significantly higher than the added spike concentration, preventing accurate evaluation of the spike recovery.

No other anomalies associated with the analysis of these samples were observed.

Approved by Lisa A. Jomeinglin

Results flagged with an asterisk (*) indicate values outside control criteria.

Results flagged with a pound (#) indicate the control criteria is not applicable.

Percent recoveries and relative percent differences (RPD) are determined by the software using values in the calculation which have not been rounded.

1 INTRODUCTION

This report presents the findings of the data validation of eight water samples and associated quality control samples analyzed for total and dissolved metals and for conventional chemistry parameters, and reported in sample delivery group K1500604. The parameters and analytical methods are listed in Table 1-1.

The samples received a Stage 2B validation, which included a review of all laboratory summary forms of quality control results and instrument performance data. The data validation was based upon criteria described in the U.S. Environmental Protection Agency's (EPA) functional guidelines for inorganic data review (USEPA 2010) and the referenced analytical methods.

The quality assurance and quality control (QA/QC) parameters reviewed are discussed in Section 2. All electronic data deliverables were compared to the hardcopy data packages, and 10% of the results were verified. Qualifiers resulting from the validation process were entered into the project database. A reason code indicating the reason for qualification was also entered into the database. The definitions of the data qualifiers used are provided in Table 1-2 and descriptions of the reason codes used are provided in Table 1-3. For example, if a data point were estimated due to laboratory blank contamination, the qualifier "U" and the reason code "LB" would be entered into the database, indicated as U-LB in the discussion of findings in Section 2.

2 FINDINGS

The following sections describe the findings of the data validation.

2.1 PARAMETERS REVIEWED

The QA/QC parameters reviewed for each analytical parameter are discussed below and are listed in Table 2-1.

2.2 SAMPLE RECEIPT AND HOLDING TIMES

Samples were received with complete chain-of-custody (COC) forms and in good condition, with the exception noted below. All analyses were conducted within the holding times in the referenced methods.

The ALS Environmental (ALS) courier did not fill in the "Relinquished By" information on the COC form.

2.3 BLANKS

Laboratory blanks were analyzed as required by the referenced analytical methods. One equipment blank was collected along with the samples. Target analytes were not detected in any of the laboratory or equipment blanks, with the exceptions noted below.

Dissolved Organic Carbon: Dissolved organic carbon (DOC) was detected at a concentration less than the method reporting limit (MRL) in the method blank. The detected DOC result in the equipment blank ERB2015012001 was qualified as not detected (U-LB) and no qualifiers were assigned based on the detection in the equipment blank.

DOC was detected in two continuing calibration blanks (CCBs) at concentrations less than the MRL. DOC results in the associated samples were either not detected or DOC concentrations were greater than the MRL, and no qualifiers were assigned.

Total Alkalinity: Total alkalinity was detected at a concentration less the MRL in the method blank. Total alkalinity results in the associated samples were greater than the MRL, and no qualifiers were assigned.

Metals: Hardness, calcium, lead, magnesium, and zinc were detected at concentrations less than the MRL in the method blank, and the following actions were taken:

- The hardness, calcium, and zinc concentrations in the associated samples were greater than the MRL, and no qualifiers were assigned.
- Lead and magnesium concentrations less than the MRL in the associated samples were qualified as not detected (U-LB).

Hardness, total calcium, total manganese, and dissolved manganese were detected at concentrations above the MRL in equipment blank ERB2015012001. Additionally, total lead, total nickel, and dissolved nickel were detected at concentrations less than the MRL. The following actions were taken:

- Hardness, total calcium, total manganese, and dissolved manganese concentrations were greater than 10 times the equipment blank concentration in the associated samples, and no qualifiers were assigned.
- Total nickel and dissolved nickel concentrations were greater than the MRL in the associated samples, and no qualifiers were assigned.
- Total lead concentrations less the MRL in the associated samples were qualified as not detected (U-FB).

Cadmium, lead, magnesium, manganese, and nickel were detected at concentrations less than the MRL in the initial calibration blanks, and the following actions were taken:

- Total and dissolved manganese concentrations in the associated samples were greater than the MRL and no qualifiers were assigned.
- Total and dissolved cadmium, lead, magnesium, and nickel concentrations less the MRL in the associated samples were qualified as not detected (U-LB).

Calcium was reported as a negative concentration with an absolute value less than the MRL in CCB1. The calcium concentrations were greater than 10 times the MRL in the associated samples, and no qualifiers were assigned.

Magnesium was detected at a concentration less than the MRL in CCB2. Total and dissolved magnesium concentrations less the MRL in the associated samples were qualified as not detected (U-LB).

Cadmium and lead were detected at concentrations less than the MRL in CCB3. Total cadmium and lead concentrations less the MRL in the associated samples were qualified as not detected (U-LB).

Manganese was detected at a concentration less than the MRL in CCB4. Total and dissolved manganese concentrations were greater than the MRL in the associated samples, and no qualifiers were assigned.

Manganese was detected at a concentration less than the MRL in CCB5. Additionally, nickel was reported as negative concentration with absolute values less than the MRL. The following actions were taken:

- Total and dissolved manganese concentrations in the associated samples were greater than the MRL, and no qualifiers were assigned.
- Total and dissolved nickel concentrations less than 10 times the MRL in the associated samples were estimated (J-LB).

2.4 MATRIX SPIKES/MATRIX SPIKE DUPLICATES

Matrix spike analyses were performed at the appropriate frequency of one per analytical batch for metals, chloride, sulfate, and DOC. Matrix spike duplicates were submitted with the chloride and sulfate analyses. The percent recoveries and relative percent differences (RPDs) of all matrix spikes and matrix spike duplicates were generally within the laboratory control limits, with the exceptions noted below.

Metals: The percent recovery value of 200% for manganese in the matrix spike analysis of sample GW2015011901 was greater than the upper control limit of 125%. Because the concentration of manganese in the parent sample was greater than 4 times the amount spiked, the control limits do not apply and no qualifiers were assigned.

2.5 LABORATORY CONTROL SAMPLES

Laboratory control samples were analyzed at the appropriate frequency of one per analytical batch for metals and conventional chemistry parameters. The percent recoveries of all laboratory control samples were within the laboratory control limits.

2.6 DUPLICATES

Laboratory duplicate analyses were performed at the appropriate frequency of one per analytical batch for metals and conventional chemistry parameters. RPDs were within the laboratory control limits.

2.7 FIELD REPLICATES

One field replicate pair was reported (GW2015012005 and GW2015012006). The EPA has not established control limits for field replicates. For this project the target control limit for field replicates is an RPD less than 35% for values greater than 5 times the MRL. For values less than

5 times the MRL, the absolute difference should be less than the MRL. The results were within these control limits.

2.8 SERIAL DILUTIONS

Serial dilution analysis was performed at the appropriate frequency of one per analytical batch for metals. The percent differences for all analytes with initial concentrations greater than 50 times the method detection limit (MDL) met the control limit of 10%.

2.9 REPORTING LIMITS AND METHODOLOGY

The MDLs and MRLs were evaluated against the limits in Table B-1 of the *Work Plan for Additional Groundwater Sampling of Beach and Bank Wells Evraz Oregon Steel* (AECOM 2012). The reported MDLs and MRLs were consistent with the target MDLs and MRLs, with the exceptions noted below.

Conventional Chemistry Parameters: Samples that were analyzed at dilutions are noted below. The MDLs and MRLs were elevated accordingly:

- Samples GW2015011902, GW2015012005, and GW2015012006 were analyzed at 2-fold dilutions, sample GW2015011903 was analyzed at a 5-fold dilution, and samples GW2015011901 and GW2015012004 were analyzed at 20-fold dilutions for high chloride concentrations.
- Sample GW2015011903 was analyzed at a 2-fold dilution and sample GW2015012004 was analyzed at a 4-fold dilution for high DOC concentrations.
- All samples, except sample ERB2015012001, were analyzed at 2-fold dilutions for high sulfate concentrations.

The MDLs and MRLs for alkalinity in all samples were above the target MDL and MRL of 0.6 and 2 µg/L, respectively.

Metals: Samples GW2015011903, GW2015012004, and GW2015012007 were analyzed at 50-fold dilutions because of high manganese concentrations. The MDLs and MRLs were elevated accordingly.

2.10 INITIAL CALIBRATION

Metals, chloride, DOC, and sulfate initial calibration verifications were analyzed at the appropriate frequency and met the acceptance criteria stated in EPA's functional guidelines for inorganic data review (USEPA 2010).

2.11 CONTINUING CALIBRATION VERIFICATION

Metals, chloride, DOC, and sulfate continuing calibration verifications were analyzed at the appropriate frequency and met the acceptance criteria stated in EPA's functional guidelines for inorganic data review (USEPA 2010).

2.12 INTERFERENCE CHECKS

The interference check sample was analyzed at the beginning of each analytical sequence and met the acceptance criteria stated in the EPA's functional guidelines for inorganic data review (USEPA 2010).

2.13 INTERNAL STANDARDS

Internal standards were added to all samples analyzed for metals by Method 6020A. The internal standard relative intensities for all samples met the acceptance criteria stated in EPA's functional guidelines for inorganic data review (USEPA 2010).

3 OVERALL ASSESSMENT

The following sections provide an overall assessment.

3.1 DATA QUALIFICATION

A total of 160 results were reported. A total of 21 results (13%) were qualified; the number of results qualified is summarized by reason in Table 3-1. A summary of all qualified results is presented in Table 3-2.

A number of metals results were qualified as not detected because of results observed in the associated laboratory blanks or equipment blank.

The total and dissolved nickel results in the equipment blank were qualified as estimated because of a low instrument bias observed in the associated laboratory blank.

No results were rejected and completeness was 100%.

3.2 DATA USABILITY

The data meet the criteria set forth in the referenced quality assurance documents, with the exceptions noted above. All results are acceptable for their intended use.

USEPA. 1974. Method 415.1. Total organic carbon in water (combustion or oxidation). 1974. U.S. Environmental Protection Agency, Washington, DC.

USEPA. 1993. Method 300.0. Determination of inorganic anions by ion chromatography. Revision 2.1, August 1993. U.S. Environmental Protection Agency, Inorganic Chemistry Branch, Chemistry Research Division. Cincinnati, OH.

USEPA. 2007a. SW-846: Test methods for evaluating solid wastes physical/chemical methods, Method 6020A, inductively coupled plasma-mass spectrometry. Revision 1, February 2007. U.S. Environmental Protection Agency, Washington, DC.

USEPA. 2007b. SW-846: Test methods for evaluating solid wastes physical/chemical methods, Method 6020A, inductively coupled plasma-atomic emission spectrometry. Revision 3, February 2007. U.S. Environmental Protection Agency, Washington, DC.

USEPA. 2010. USEPA Contract Laboratory Program national functional guidelines for inorganic Superfund data review. USEPA-540-R-10-01. January 2010. U.S. Environmental Protection Agency, Office of Superfund Remediation and Technology Innovation, Washington, DC.

TABLES

Table 1-1. Analytical Parameters and Methods

Laboratory	Analytical Parameter	Analytical Method	Reference
ALS	Alkalinity	SM2320B	APHA et al. (2012)
	Chloride	EPA 300.0	USEPA (1993)
	Dissolved Organic Carbon	EPA 415.1	USEPA (1974)
	Hardness as CaCO ₃	SM2340B	APHA et al. (2012)
	Sulfate	EPA 300.0	USEPA (1993)
	Total and Dissolved Metals	EPA 6010C/6020A	USEPA (2007a)
	Total Suspended Solids	SM2540D	APHA et al. (2012)

Notes:

ALS = ALS Environmental; Kelso, WA

dissolved metals = arsenic, cadmium, lead, manganese, nickel

SM = Standard Method for the Examination of Water and Wastewater

total metals = arsenic, cadmium, calcium, lead, magnesium, manganese, nickel, potassium, sodium

Table 1-2. Definition of Data Qualifiers

Data Qualifier	Definition
U	The material was analyzed for, but was not detected. The associated numerical value is the sample quantitation limit.
UJ	Estimated and not detected. The analyte is considered to be not detected at the reported value, and the associated numerical value is an estimated value.

Table 1-3. Definition of Data Validation Reason Codes

Reason Code	Definition
FB	Field blank
LB	Laboratory blank

Table 2-1. QA/QC Parameters Reviewed

QA/QC Parameters	Analytical Parameter						
	Alkalinity	Chloride	Dissolved Organic Carbon	Hardness as CaCO ₃	Sulfate	Total and Dissolved Metals	Total Suspended Solids
	SM2320B	EPA 300.0	EPA 415.1	SM2340B	EPA 300.0	EPA 6010C /6020A	SM2540D
Sample Receipt and Holding Times	D	D	D	D	D	D	D
Blanks	D	+	Q	D	+	Q	+
MS/MSD	NA	+	+	NA	+	D	NA
LCS	+	+	+	NA	+	+	+
Duplicates	+	+	+	+	+	+	+
Serial Dilutions	NA	NA	NA	NA	NA	+	NA
MRL/MDL & Methodology	D	D	D	+	D	D	+
Initial Calibration Verification	NA	+	+	D	+	+	NA
Continuing Calibration Verification	NA	+	+	D	+	+	NA
Interference Checks	NA	NA	NA	D	NA	+	NA
Internal Standards	NA	NA	NA	D	NA	+	NA

Notes:

+ = All QA/QC criteria met

D = Data are discussed in the report. QA/QC criteria were not met; however no data were qualified.

Q = Data were qualified and are discussed in the report.

LCS = laboratory control sample

MDL = method detection limit

MRL = method reporting limit

MS/MSD = matrix spike/matrix spike duplicate

Metals = arsenic, cadmium, chromium, copper, lead, manganese, zinc

NA = not applicable

QA/QC = quality assurance and quality control

Table 3-1. Summary of Qualified Data Points by Reason

Data Qualification Reason	Number of Data Points Estimated	Number of Data Points Qualified	Number of Data Points Rejected
		Not Detected	
Equipment blank contamination	-	4	-
Method blank contamination	2	21	-

Notes:

- = none

Table 3-2. Summary of Qualified Data

SDG	Sample	Analyte	Result	Method Reporting Limit	Lab Qualifier	DV Qualifier	DV Qualifier Reason	Units
K1500604	GW2015011901	Cadmium	0.019	0.02	J	U	LB	µg/L
K1500604	GW2015011901	Dissolved Cadmium	0.013	0.02	J	U	LB	µg/L
K1500604	GW2015011901	Dissolved Lead	0.009	0.02	J	U	LB	µg/L
K1500604	GW2015011903	Cadmium	0.006	0.02	J	U	LB	µg/L
K1500604	GW2015011903	Lead	0.008	0.02	J	U	LB,FB	µg/L
K1500604	GW2015012004	Cadmium	0.012	0.02	J	U	LB	µg/L
K1500604	GW2015012004	Dissolved Cadmium	0.008	0.02	J	U	LB	µg/L
K1500604	GW2015012005	Cadmium	0.005	0.02	J	U	LB	µg/L
K1500604	GW2015012005	Lead	0.007	0.02	J	U	LB,FB	µg/L
K1500604	GW2015012005	Dissolved Lead	0.005	0.02	J	U	LB	µg/L
K1500604	GW2015012006	Cadmium	0.01	0.02	J	U	LB	µg/L
K1500604	GW2015012006	Lead	0.006	0.02	J	U	LB,FB	µg/L
K1500604	GW2015012007	Cadmium	0.011	0.02	J	U	LB	µg/L
K1500604	GW2015012007	Lead	0.016	0.02	J	U	LB,FB	µg/L
K1500604	GW2015012007	Dissolved Cadmium	0.011	0.02	J	U	LB	µg/L
K1500604	GW2015012007	Dissolved Lead	0.009	0.02	J	U	LB	µg/L
K1500604	ERB2015012001	Lead	0.006	0.02	J	U	LB	µg/L
K1500604	ERB2015012001	Magnesium	2.2	5	J	U	LB	µg/L
K1500604	ERB2015012001	Nickel	0.09	0.2	J	UJ	LB	µg/L
K1500604	ERB2015012001	Dissolved Organic Carbon	0.22	0.5	J	U	LB	mg/L
K1500604	ERB2015012001	Dissolved Nickel	0.05	0.2	J	UJ	LB	µg/L

Notes:

DV = data validation

FB = equipment blank contamination

LB = laboratory blank contamination

SDG = sample delivery group

J = The associated numerical value is an estimated quantity.

U = The material was analyzed for, but was not detected. The associated numerical value is the sample quantitation limit.

UJ = Estimated and not detected. The analyte is considered to be not detected at the reported value, and the associated numerical value is an estimate.
